OpenWhisk Package Specification

Version 0.8, Working Draft 09, Revision 1

Notational Conventions

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119.

Introduction

OpenWhisk™ is an open source, distributed Serverless computing project.
Specifically, it is able to execute application logic (*Actions*) in response to events (*Triggers*) from external sources (*Feeds*) governed by simple conditional logic (*Rules*) around the event data.

It provides a programming model for registering and managing *Actions*, *Triggers* and *Rules* supported by a REST-based Command Line Interface (CLI) along with tooling to support packaging and catalog services.

The project includes a catalog of built-in system and utility *Actions* and *Feeds*, along with a robust set of samples that demonstrate how to integrate OpenWhisk with various external service providers (e.g., GitHub, Slack, etc.) along with several platform and run-time Software Development Kits (SDKs).

The code for the Actions, along with any support services implementing *Feeds*, are packaged according to this specification to be compatible with the OpenWhisk catalog and its tooling. It also serves as a means for architects and developers to model OpenWhisk package Actions as part of full, event-driven services and applications providing the necessary information for artifact and data type validation along with package management operations.

Compatibility

This specification is intended to be compatible with the following specifications:

- *OpenWhisk API which is defined as an OpenAPI document:*
  - https://raw.githubusercontent.com/openwhisk/openwhisk/master/core/controller/src/main/resources/whiskswagger.json
- *OpenAPI Specification when defining REST APIs and parameters:*
  - https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md

Revision History

Version	Date	Notes
0.8.1	2016-11-03	Initial public point draft, Working Draft 01
0.8.2	2016-12-12	Working Draft 02, Add. Use cases, examples
0.8.3	2017-02-02	Working Draft 03, Add use cases, examples, $ notation
0.8.4	2017-04-18	Working Draft 04, Support JSON parameter type; Clarify use of Parameter single-line grammar and inferred types. Add support for API Gateway mappings. Add support for Web Actions
0.8.5	2017-04-21	Add support for "dependencies", that is allow automatic deployment of other OpenWhisk packages (from GitHub) that the current package declares as a dependency.
0.8.6	2017-07-25	• Clarified requirements for $ dollar notation. • Updated conceptual Manifest/Deployment File processing images.
0.8.7	2017-08-24	• Added explicit Application entity and grammar. • Added API listing to Package entity. • Cleaned up pseudo-grammar which contained various uses of credentials in places not intended. • Fixed Polygon Tracking example (indentation incorrect).
0.8.8	2017-08-29	• Created a simplified API entity (i.e., "api") grammar that allows multiple sets of named APIs for the same basepath. • Acknowledge PHP as supported runtime (kind). • Added "sequences" entity as a convenient way to declare action sequences in the manifest. Updated supported runtime values.
0.8.9 0.8.9.1	2017-09-22 2017-09-29	• Clarified "version" key requirements for Package (required) and Action (optional); removed from shared entity schema. • Made "license" key optional for package. • keyword "package" (singular) and "packages" (plural) both allowed. • Adjusted use case examples to reflect these changes. • Rework of schema use cases into full, step-by-step examples. • Spellcheck, fixed bugs, update examples to match web-based version.

Table of Contents

Programming Model

OpenWhisk Entities

OpenWhisk uses the following entities to describe its programming model:

Action

A stateless, relatively short-running function (*on the order of seconds or even milliseconds*) invoked as an event handler.

Trigger

The name for a class of events. Triggers represent the events (and their data) themselves without any concept of how they were generated.

Rule

A mapping from a Trigger to an Action which may contain simple conditional logic. OpenWhisk evaluates incoming events (that belong to a Trigger) and invokes the assigned Action (event handler).

Event Source

An Event Source is the descriptor (edge) for an Event Producer (or provider). It describes the Event Format(s) produced, as well as any configuration and subscription capabilities.

Feed

A Feed is an optional service that represents and controls the stream which all belong to a Trigger. A feed provides operations called **feed actions** which handle creating, deleting, pausing, and resuming the stream of events. The feed action typically interacts with external services which produce the events

Package

A named, shared collection of Actions and Feeds. The goal of this specification is to describe OpenWhisk packages and their component entities and resources to enable an open-ecosystem.

Packages are designed to be first-class entities within the OpenWhisk platform to be used by tooling such as catalogs (repositories), associated package managers, installers, etc.

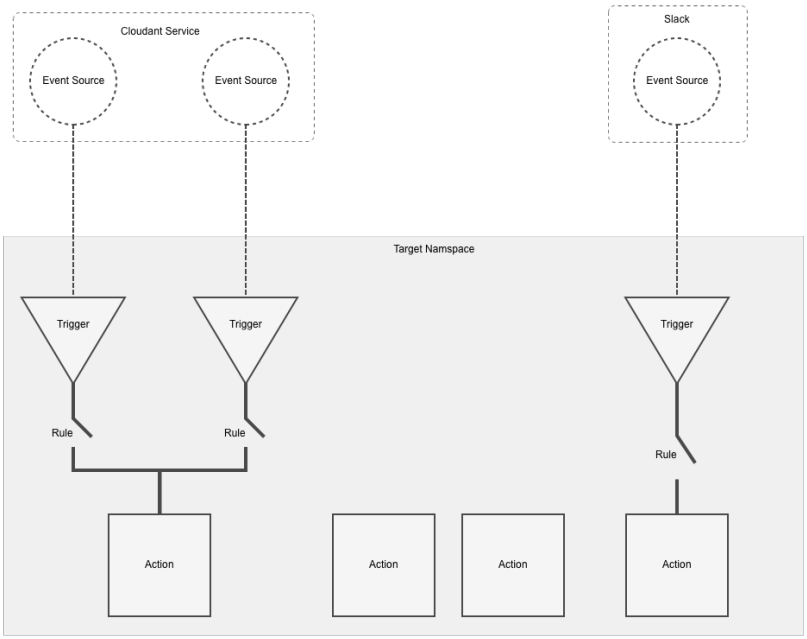
Note: Not all actions must belong to packages, but can exist under a namespace.

Cardinality

Trigger to Action

With the appropriate set of Rules, it's possible for a single Trigger (event) to invoke multiple Actions, or for an Action to be invoked as a response to events from multiple Triggers.

Conceptual representation



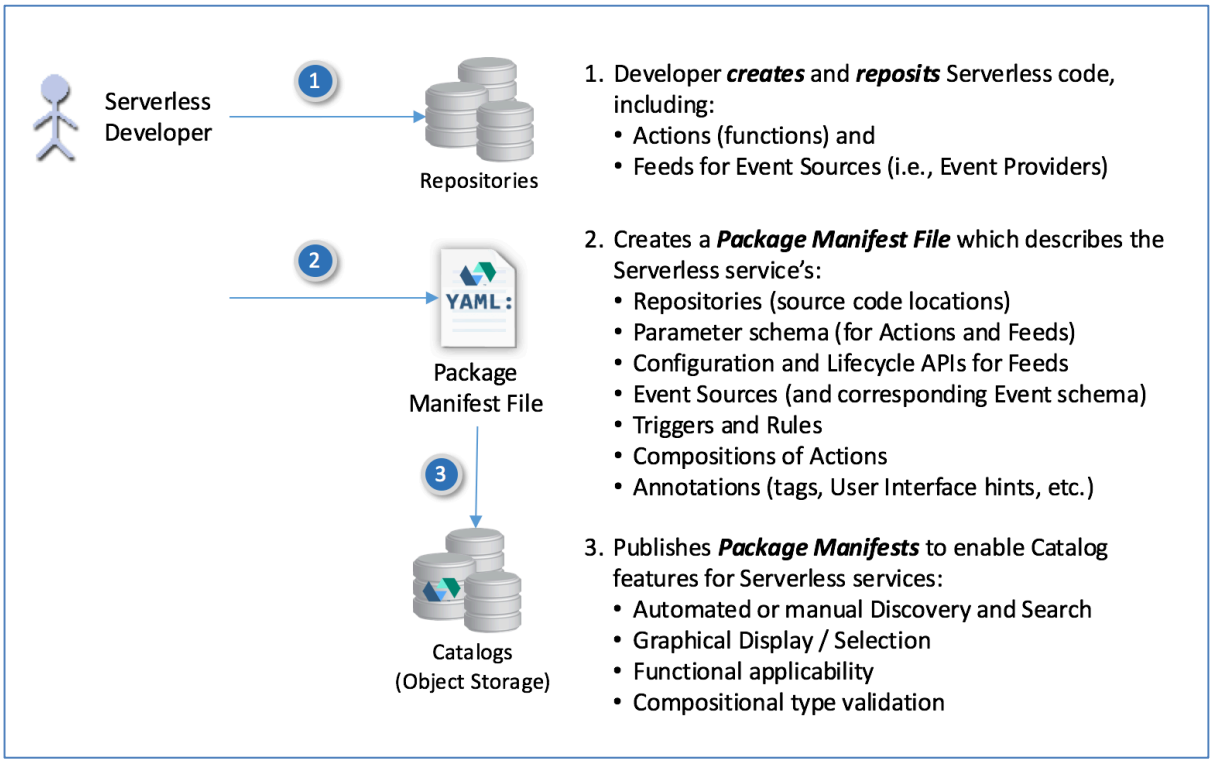
Package processing

This document defines two file artifacts that are used to deploy Packages to a target OpenWhisk platform; these include:

- **Package Manifest file**: Contains the Package definition along with any included Action, Trigger or Rule definitions that comprise the package. This file includes the schema of input and output data to each entity for validation purposes.
- **Deployment file**: Contains the values and bindings used configure a Package to a target OpenWhisk platform provider's environment and supply input parameter values for Packages, Actions and Triggers. This can include Namespace bindings, security and policy information.

Conceptual Package creation and publishing

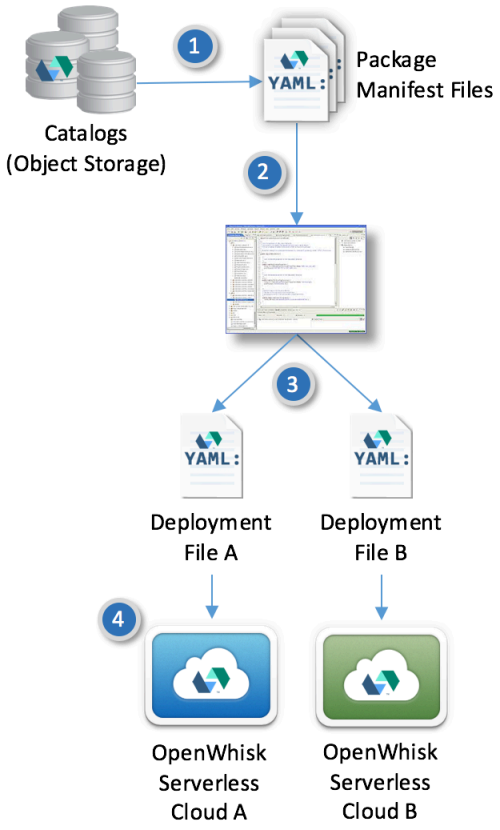
The following diagram illustrates how a developer would create OpenWhisk code artifacts and associate a Package Manifest file that describes them for deployment and reuse.



Conceptual tooling integration and deployment

The following diagram illustrates how Package manifests can be leveraged by developer tooling to integrate OpenWhisk Serverless functions.

1. Developer ***searches*** and ***discovers*** OpenWhisk packages described by the ***Package Manifest*** in one or more Catalogs, that can:
   - Help analyze, augment and annotate application information and data.
   - Add value added functionality to a base application or workflow.
2. Imports Open ***Package Manifest Files*** and related code and artifacts into development tooling, including:
   - Project and Application (source code) Repositories
   - Integrated Development Environments (IDEs)
   - Cloud-based design, workflow and application workspaces.
3. Creates OpenWhisk ***Deployment Files*** for one or more target OpenWhisk enabled Clouds, with
   - Parameter values for desired target environment
   - Appropriate Credentials and configurations for chosen Event Sources and Feeds.
4. Deploys ***Packages*** (i.e., Actions, Triggers, Feeds, etc.) to OpenWhisk enabled Clouds, using,
   - ***Package Manifest*** and ***Deployment File(s)***.



Notes

- Deployment Files are optional. Deployment can be fully accomplished with simply the Manifest File.

Composition

Action Sequence

An Action that is a sequenced composition of 2 or more existing Actions. The Action Sequence can be viewed as a named pipe where OpenWhisk can automatically take the output of a first Action 'A' in a declared sequence and provides it as input to the next Action 'B' in the sequence and so on until the sequence completes.

Note: This composition technique allows the reuse of existing action implementations treating them as "building blocks" for other Actions.

Namespacing

Every OpenWhisk entity (i.e., Actions, Feeds, Triggers), including packages, belongs in a *namespace.*

The fully qualified name of any entity has the format:

```
/<namespaceName>[/<packageName>]/<entityName>
```

The namespace is typically provided at bind-time by the user deploying the package to their chosen OpenWhisk platform provider.

Note: The `/whisk.system` namespace is reserved for entities that are distributed with the OpenWhisk system.

Entity Names

The names of all entities, including actions, triggers, rules, packages, and namespaces, are a sequence of characters that follow the following format:

- The first character SHALL be an alphanumeric character, a digit, or an underscore.
- The subsequent characters MAY be alphanumeric, digits, spaces, or any of the following:

  `_, @, ., -`
- The last character SHALL NOT be a space.
- The maximum name length of any entity name is 256 characters (i.e., ENTITY_NAME_MAX_LENGTH = 256).

Valid entity names are described with the following regular expression (Java metacharacter syntax):

```
"\A([\w]|[\w][\w@ .-]{0,${ENTITY_NAME_MAX_LENGTH - 2}}[\w@.-])\z"
```

Definitions

Activation

An invocation or "run" of an action results in an activation record that is identified by a unique activation ID. The term Activation is short-hand for the creation of this record and its information.

Repository

A location that provides storage for sets of files, as well as the history of changes made to those files.

Project

A description of a software application which enables management of its design, implementation, source control, monitoring and testing.

Application

A computer program designed to perform a group of coordinated functions, tasks, or activities to achieve some result or user benefit.

[Cloud] Service

Any resource, including a functional task, that is provided over the Internet. This includes delivery models such as *Platform as a Service* (PaaS), *Infrastructure as a* Service (IaaS), as well as *Serverless*.

Specification

This specification utilizes the YAML language, a superset of JSON, which supports key features for packaging descriptors and configuration information such as built-in data types, complex data types,

anchors (relational information), files, comments and can embed other data formats such as JSON and XML easily.

YAML Types

Many of the types we use in this profile are *built-in* types from the YAML 1.2 specification (i.e., those identified by the "tag:yaml.org,2002" version tag).

The following table declares the valid YAML type URIs and aliases that SHALL be used when defining parameters or properties within an OpenWhisk package manifest:

Type Name	Type URI	Notes
`string`	tag:yaml.org,2002:str (default)	Default type if no type provided
`integer`	tag:yaml.org,2002:int	Signed. Includes large integers (i.e., long type)
`float`	tag:yaml.org,2002:float	Signed. Includes large floating point values (i.e., double type)
`boolean`	tag:yaml.org,2002:bool	This specification uses lowercase 'true' and lowercase 'false'
`timestamp`	tag:yaml.org,2002:timestamp (see YAML-TS-1.1)	ISO 8601 compatible.
`null`	tag:yaml.org,2002:null	Different meaning than an empty string, map, list, etc.

Requirements

- The '`string`' type SHALL be the default type when not specified on a parameter or property declaration.
- All '`boolean`' values SHALL be lowercased (i.e., '`true`' or '`false`').

OpenWhisk Types

In addition to the YAML built-in types, OpenWhisk supports the types listed in the table below. A complete description of each of these types is provided below.

Type Name	Description	Notes
`version`	tag:maven.apache.org:version (see Maven version)	Typically found in modern tooling (i.e., "package@version" or "package:version" format).
`string256`	long length strings (e.g., descriptions)	A string type limited to 256 characters.
`string64`	medium length strings (e.g., abstracts, hover text)	A string type limited to 64 characters.
`string16`	short length strings (e.g., small form-factor list displays)	A string type limited to 16 characters.
`json`	The parameter value represents a JavaScript Object Notation (JSON) data object.	The deploy tool will validate the corresponding parameter value against JSON schema. Note: The implied schema for JSON the JSON Schema (see http://json-schema.org/).

`scalar-unit`	Convenience type for declaring common scalars that have an associated unit. For example, "10 msec.", "2 Gb", etc.)	Currently, the following scalar-unit subtypes are supported: • scalar-unit.size • scalar-unit.time See description below for details.
`schema`	The parameter itself is an OpenAPI Specification v2.0 **Schema Object** (in YAML format) with self-defining schema.	The schema declaration follows the OpenAPI v2.0 specification for Schema Objects (YAML format). Specifically, see https://github.com/OAI/OpenAPI-Specification/blob/master/versions/2.0.md#schemaObject
`object`	The parameter itself is an object with the associated defined Parameters (schemas).	Parameters of this type would include a declaration of its constituting Parameter schema.

scalar-unit types

Scalar-unit types can be used to define scalar values along with a unit from the list of recognized units (a subset of GNU units) provided below.

Grammar

```
<scalar> <unit>
```

In the above grammar, the pseudo values that appear in angle brackets have the following meaning:

- `scalar`: is a required scalar value (e.g., integer).
- `unit`: is a required unit value. The unit value MUST be type-compatible with the scalar value.

Example

```
inputs:
  max_storage_size:
    type: scalar-unit.size
    default: 10 GB
  archive_period:
    type: scalar-unit.time
    default: 30 d
```

Requirements

- Whitespace: any number of spaces (including zero or none) SHALL be allowed between the scalar value and the unit value.
- It SHALL be considered an error if either the scalar or unit portion is missing on a property or attribute declaration derived from any scalar-unit type.

Recognized units for sizes (i.e., scalar-unit.size)

Unit	Description
B	byte
kB	kilobyte (1000 bytes)

Unit	Description
MB	megabyte (1000000 bytes)
GB	gigabyte (1000000000 bytes)
TB	terabyte (1000000000000 bytes)

Example

```
inputs:
  memory_size:
    type: scalar-unit.size
    value: 256 MB
```

Recognized units for times (i.e., scalar-unit.time)

Unit	Description
d	days
h	hours
m	minutes
s	seconds
ms	milliseconds
us	microseconds

Example

```
inputs:
  max_execution_time:
    type: scalar-unit.time
    value: 600 s
```

Object type example

The Object type allows for complex objects to be declared as parameters with an optional validateable schema.

```
inputs:
  person:
    type: object
    parameters: <schema>
```

Schema

This section defines all the essential schema used to describe OpenWhisk packages within a manifest.

General Requirements

- All field names in this specification SHALL be case sensitive.

map schema

The Map schema is used to define maps of key values within OpenWhisk entities.

Single-line grammar

```
{ <key_1>: <value_1>, ..., <key_n>: <value_n> }
```

Multi-line grammar

```
# Where 'key_n' is a type <string> and 'value_n' is type <any>.
<key_1>: <value_1>
...
<key_n>: <value_n>
```

Examples

Single-line

```
alert_levels: { "high": "red", "medium": "yellow", "low": green }
```

Multi-line

```
alert_levels:
  "high": "red"
  "medium": "yellow"
  "low": green
```

Parameter schema

The Parameter schema is used to define input and/or output data to be used by OpenWhisk entities for the purposes of validation.

Fields

Key Name	Required	Value Type	Default	Description
type	no	`<any>`	`string`	Optional valid type name or the parameter's value for validation purposes. By default, the type is `string`.
description	no	`string256`	N/A	Optional description of the Parameter.
value	no	`<any>`	N/A	The optional user supplied value for the parameter. Note: this is not the default value, but an explicit declaration which allows simple usage of the Manifest file without a Deployment file..
required	no	`boolean`	`true`	Optional indicator to declare the parameter as required (i.e., `true`) or optional (i.e., `false`).
default	no	`<any>`	N/A	Optional default value for the optional parameters. This value **MUST** be type compatible with the value declared on the parameter's `type` field.
status	no	`string`	`supported`	Optional status of the parameter (e.g., `deprecated`, `experimental`). By default a parameter is without a declared status is considered supported.

Key Name	Required	Value Type	Default	Description
schema	no	`<schema>`	N/A	The optional schema if the '`type`' key has the value '`schema`'. The value would include a **Schema Object** (in YAML) as defined by the OpenAPI Specification v2.0. This object is based upon the JSON Schema Specification.
properties	no	`<list of parameter>`	N/A	The optional properties if the '`type`' key has the value '`object`'. Its value is a listing of Parameter schema from this specification.

Requirements

- The "schema" key's value MUST be compatible with the value provided on both the "type" and "value" keys; otherwise, it is considered an error.

Notes

- The "type" key acknowledges some popular schema (e.g., JSON) to use when validating the value of the parameter. In the future additional (schema) types may be added for convenience.

Grammar

Single-line

```
<parameterName>: <YAML type> | scalar-unit | json
```

- Where `<YAML type>` is inferred to be a YAML type as shown in the YAML Types section above (e.g., `string`, `integer`, `float`, `boolean`, etc.).
- If you wish the parser to validate against a different schema, then the multi-line grammar MUST be used where the value would be supplied on the keyname "value" and the type (e.g., 'json') and/or schema (e.g., OpenAPI) can be supplied.

Multi-line

```
<parameterName>:
  type: <any>
  description: <string>
  required: <boolean>
  default: <any>
  status: <string>
  schema: <OpenAPI Schema Object>
```

Status values

Status Value	Description
`supported` (default)	Indicates the parameter is supported. This is the implied default status value for all parameters.
`experimental`	Indicates the parameter MAY be removed or changed in future versions.
`deprecated`	Indicates the parameter is no longer supported in the current version and MAY be ignored.

Dollar Notation ($) schema for values

In a Manifest or Deployment file, a parameter value may be set from the local execution environment by using the dollar ($) notation to denote names of local environment variables which supply the value to be inserted at execution time.

Syntax

```
<parameter>: $<local_environment_variable_name>
```

Example

```
...
  inputs:
    userName: $DEFAULT_USERNAME
```

Requirements

- Processors or tooling that encounter ($) Dollar notation and are unable to locate the value in the execution environment SHOULD resolve the value to be the default value for the type (e.g., an empty string ("") for type '`string`').
- A value binding provided on the 'value' key takes precedence over a value binding on the 'default' key.

Notes

- Processors or tooling that encounter ($) Dollar notation for values should attempt to locate the corresponding named variables set into the local execution environment (e.g., where the tool was invoked) and assign its value to the named input parameter for the OpenWhisk entity.
- This specification does not currently consider using this notation for other than simple data types (i.e., we support this mechanism for values such as strings, integers, floats, etc.) at this time.

Shared Entity Schema

The Entity Schema contains fields that are common (shared) to all OpenWhisk entities (e.g., Actions, Triggers, Rules, etc.).

Fields

Key Name	Required	Value Type	Default	Description
description	no	`string256`	N/A	The optional description for the Entity.
displayName	no	`string16`	N/A	This is the optional name that will be displayed on small form-factor devices.
annotations	no	`map of <string>`	N/A	The optional annotations for the Entity.

Grammar

```
description: <string256>
displayName: <string16>
annotations: <map of <string>>
```

Requirements

- Non-required fields MAY be stored as "annotations" within the OpenWhisk framework after they have been used for processing.
- Description string values SHALL be limited to 256 characters.
- DisplayName string values SHALL be limited to 16 characters.
- Annotations MAY be ignored by target consumers of the Manifest file as they are considered data non-essential to the deployment of management of OpenWhisk entities themselves.
    - Target consumers MAY preserve (persist) these values, but are not required to.
- For any OpenWhisk Entity, the maximum size of all Annotations SHALL be 256 characters.

Notes

- Several, non-normative Annotation keynames and allowed values for (principally for User Interface (UI) design) may be defined below for optional usage.

Action entity

The Action entity schema contains the necessary information to deploy an OpenWhisk function and define its deployment configurations, inputs and outputs.

Fields

Key Name	Required	Value Type	Default	Description
version	no	`version`	N/A	The optional user-controlled version for the Action.
function	yes	`string`	N/A	Required source location (path inclusive) of the Action code either • Relative to the Package manifest file. • Relative to the specified Repository.
runtime	no	`string`	N/A	The required runtime name (and optional version) that the Action code requires for an execution environment. *Note: May be optional if tooling allowed to make assumptions about file extensions.*
inputs	no	`list` of `parameter`	N/A	The optional ordered list inputs to the Action.
outputs	no	`list` of `parameter`	N/A	The optional outputs from the Action.
limits	no	`map` of limit keys and values	N/A	Optional map of limit keys and their values. *See section "Valid limit keys" below for a listing of recognized keys and values.*
feed	no	`boolean`	`false`	Optional indicator that the Action supports the required parameters (and operations) to be run as a Feed Action.
web-export	no	`boolean`	`false`	Optionally, turns the Action into a "*web actions*" causing it to return HTTP content without use of an API Gateway.

Requirements

- The Action name (i.e., `<actionName>` MUST be less than or equal to 256 characters.

- The Action entity schema includes all general Entity Schema fields in addition to any fields declared above.
- Supplying a `runtime` name without a version indicates that OpenWhisk SHOULD use the most current version.
- Supplying a runtime *major version* without a *minor version* (et al.) indicates OpenWhisk SHOULD use the most current *minor version*.
- Unrecognized `limit` keys (and their values) SHALL be ignored.
- Invalid values for known `limit` keys SHALL result in an error.
- If the Feed is a Feed Action (i.e., the `feed` key's value is set to `true`), it MUST support the following parameters:
  - **lifecycleEvent**: one of 'CREATE', 'DELETE', 'PAUSE', or 'UNPAUSE'
    - These operation names MAY be supplied in lowercase (i.e., 'create', 'delete', 'pause', etc.).
  - **triggerName**: the fully-qualified name of the trigger which contains events produced from this feed.
  - **authKey**: the Basic auth. credentials of the OpenWhisk user who owns the trigger.

Notes

- Input and output parameters are implemented as JSON Objects within the OpenWhisk framework.
- The maximum code size for an Action currently must be less than 48 MB.
- The maximum payload size for an Action (i.e., POST content length or size) currently must be less than 1 MB.
- The maximum parameter size for an Action currently must be less than 1 MB.
- if no value for runtime is supplied, the value 'language:default' will be assumed.

Grammar

```
# Note: the optional [.<type>] grammar is used for naming Web Actions.
<actionName>[.<type>]:
  <Entity schema>
  version: <version>
  function: <string>
  runtime: <name>[@<[range of ]version>]
  inputs:
    <list of parameter>
  outputs:
    <list of parameter>
  limits:
    <list of limit key-values>
  feed: <boolean>
  web-export: <boolean>
```

Example

```
my_awesome_action:
  version: 1.0
  description: An awesome action written for node.js
  function: src/js/action.js
  runtime: nodejs@>0.12<6.0
  inputs:
```

```
    not_awesome_input_value:
      description: Some input string that is boring
      type: string
  outputs:
    awesome_output_value:
      description: Impressive output string
      type: string
  limits:
    memorySize: 512 kB
    logSize: 5 MB
```

Valid Runtime names

The following runtime values are currently supported by the OpenWhisk platform.

Each of these runtimes also include additional built-in packages (or libraries) that have been determined be useful for Actions surveyed and tested by the OpenWhisk platform.

These packages may vary by OpenWhisk release; examples of supported runtimes as of this specification version include:

Runtime value	OpenWhisk kind	image name	Description
`nodejs`	nodejs	nodejsaction:latest	Latest NodeJS runtime
`nodejs@6`	nodejs:6	nodejs6action:latest	Latest NodeJS 6 runtime
`java, java@8`	java	java8action:latest	Latest Java language runtime
`python, python@2`	python:2	python2action:latest	Latest Python 2 language runtime
`python@3`	python:3	python3action:latest	Latest Python 3 language runtime
`swift, swift@2`	swift	swiftaction:latest	Latest Swift 2 language runtime
`swift@3`	swift:3	swift3action:latest	Latest Swift 3 language runtime
`swift@3.1.1`	swift:3.1.1	action-swift-v3.1.1:latest	Latest Swift 3.1.1 language runtime
`php`	php:7.1	action-php-v7.1:latest	Latest PHP language runtime
`language:default`	N/A	N/A	Permit the OpenWhisk platform to select the correct default language runtime.

Recognized File extensions

Although it is best practice to provide a runtime value when declaring an Action, it is not required. In those cases, that a runtime is not provided, the package tooling will attempt to derive the correct runtime based upon the the file extension for the Action's function (source code file). The following file extensions are recognized and will be run on the latest version of corresponding Runtime listed below:

File extension	Runtime used	Description
`.js`	nodejs	Latest Node.js runtime.

File extension	Runtime used	Description
`.java`	java	Latest Java language runtime.
`.py`	python	Latest Python language runtime.
`.swift`	swift	Latest Swift language runtime.
.php	php	Latest PHP language runtime.

Valid Limit keys

Limit Keyname	Allowed values	Default value	Valid Range	Description
`timeout`	scalar-unit.time	60000 ms	[100 ms, 300000 ms]	The per-invocation Action timeout. Default unit is assumed to be milliseconds (ms).
`memorySize`	scalar-unit.size	256 MB	[128 MB, 512 MB]	The per-Action memory. Default unit is assumed to be in megabytes (MB).
`logSize`	scalar-unit.size	10 MB	[0 MB, 10 MB]	The action log size. Default unit is assumed to be in megabytes (MB).
`concurrentActivations`	integer	1000	*See description*	The maximum number of concurrent Action activations allowed (per-namespace). *Note: This value is not changeable via APIs at this time.*
`userInvocationRate`	integer	5000	*See description*	The maximum number of Action invocations allowed per user, per minute. *Note: This value is not changeable via APIs at this time.*
`codeSize`	scalar-unit.size	48 MB	*See description*	The maximum size of the Action code. *Note: This value is not changeable via APIs at this time.*
`parameterSize`	scalar-unit.size	1 MB	*See description*	The maximum size *Note: This value is not changeable via APIs at this time.*

Notes

The default values and ranges for limit configurations reflect the defaults for the OpenWhisk platform (open source code). These values may be changed over time to reflect the open source community consensus.

Web Actions

OpenWhisk can turn any Action into a "web action" causing it to return HTTP content without use of an API Gateway. Simply supply a supported "type" extension to indicate which content type is to be returned and identified in the HTTP header (e.g., `.json`, `.html`, `.text` or `.http`).

Return values from the Action's function are used to construct the HTTP response. The following response parameters are supported in the response object.

- **`headers`**: a JSON object where the keys are header-names and the values are string values for those headers (default is no headers).
- **`code`**: a valid HTTP status code (default is 200 OK).
- **`body`**: a string which is either plain text or a base64 encoded string (for binary data).

Trigger entity

The Trigger entity schema contains the necessary information to describe the stream of events that it represents. For more information, see the document "Creating Triggers and Rules".

Fields

Key Name	Required	Value Type	Default	Description
feed	no	`string`	N/A	The optional name of the Feed associated with the Trigger.
credential	no	`Credential`	N/A	The optional credential used to access the feed service.
inputs	no	`list` of `parameter`	N/A	The optional ordered list inputs to the feed.
events	no	`list` of `Event`	N/A	The optional list of valid Event schema the trigger supports. OpenWhisk would validate incoming Event data for conformance against any Event schema declared under this key. ***Note**: This feature is not supported at this time. This is viewed as a possible feature that may be implemented along with configurable options for handling of invalid events.*

Requirements

- The Trigger name (i.e., `<triggerName>` MUST be less than or equal to 256 characters.
- The Trigger entity schema includes all general Entity Schema fields in addition to any fields declared above.

Notes

- The '`events`' key name is not supported at this time.
- The Trigger entity within the OpenWhisk programming model is considered outside the scope of the Package (although there are discussions about changing this in the future). This means that Trigger and API information will not be returned when using the OpenWhisk Package API:
  - `wsk package list <package name>`
- However, it may be obtained using the Trigger API:
  - `wsk trigger list -v`

Grammar

```
<triggerName>:
  <Entity schema>
  feed: <feed name>
  credential: <Credential>
```

```
  inputs:
    <list of parameter>
```

Example

```
triggers:
  everyhour:
    feed: /whisk.system/alarms/alarm
```

Rule entity

The Rule entity schema contains the information necessary to associates one trigger with one action, with every firing of the trigger causing the corresponding action to be invoked with the trigger event as input. For more information see the document "Creating Triggers and Rules".

Fields

Key Name	Required	Value Type	Default	Description
trigger	yes	`string`	N/A	Required name of the Trigger the Rule applies to.
action	yes	`string`	N/A	Required name of the Action the Rule applies to.
rule	no	`regex`	true	The optional regular expression that determines if the Action is fired. Note: In this version of the specification, only the expression "`true`" is currently supported.

Requirements

- The Rule name (i.e., `<ruleName>`) MUST be less than or equal to 256 characters.
- The Rule entity schema includes all general Entity Schema fields in addition to any fields declared above.

Requirements

- OpenWhisk only supports a value of '`true`' for the '`rule`' key's value at this time.

Grammar

```
<ruleName>:
  description: <string>
  trigger: <string>
  action: <string>
  rule: <regex>
```

Example

```
my_rule:
  description: Enable events for my Action
  trigger: my_trigger
  action: my_action
```

Feed entity

The OpenWhisk Feed entity schema contains the information necessary to describe a configurable service (that may work with an existing network accessible service) to produce events on its behalf thereby acting as an Event Source.

At this time, the Package Manifest simply provides the information to describe a Feed (service), its Action, lifecycle operations (along with their parameters) and the associated service it works with. In the future, we intend to allow more granular ability to manage Feeds directly using their operations.

Fields

Key Name	Required	Value Type	Default	Description
location	no	string	`N/A`	The URL for the Feed service which can be used by the OpenWhisk platform for registration and configuration.
credential	no	string	`N/A`	Contains either: • A credential string. • The optional name of a credential (e.g., token) that must be used to access the Feed service. Note: this would be defined elsewhere, perhaps as an input parameter to the Package.
operations	no	list of operations	`N/A`	The list of operations (i.e., APIs) the Feed supports on the URL provided described, by default, using the OpenAPI (f.k.a. "Swagger") specification schema.
operation_type	no	openwhisk | openapi@<version>	`openwhisk`	The specification format for the operation definitions.
action	no	string	`N/A`	The optional name of the Action if this is a Feed Action, that is, the Feed service implementation is an OpenWhisk Action.

Requirements

- The Feed name (i.e., `<feedName>` MUST be less than or equal to 256 characters.
- The Feed entity schema includes all general Entity Schema fields in addition to any fields declared above.
- If the `action` field is set, the corresponding Action definition and function (code) MUST be a valid Feed Action.
- The location and credential SHOULD be supplied if the Feed is not a Feed action using a Deployment File.
- Operation names in manifests MAY be lower or upper cased (e.g., "create" or "CREATE").

Grammar

```
<feedName>:
  location: <string>
  credential: <string>
  operations:
    <list of operations>
```

```
  action: <string>
```

Example

The following example shows the mandatory operations for Feed Actions.

```
my_feed:
  description: A simple event feed
  location: https://my.company.com/services/eventHub
  # Reference to a credential defined elsewhere in manifest
  credential: my_credential
  operations:
    # Note: operation names in manifests MAY be lower or upper cased.
    create | CREATE:
      inputs:
        <parameters>
    delete | DELETE:
      inputs:
        <parameters>
    pause | PAUSE:
      inputs:
        <parameters>
    unpause | UNPAUSE:
      inputs:
        <parameters>
    # Additional, optional operations
    ...
```

Discussion

For a description of types of Feeds and why they exist, please see:

- https://github.com/apache/incubator-openwhisk/blob/master/docs/feeds.md.

Feed Actions

OpenWhisk supports an open API, where any user can expose an event producer service as a **feed** in a **package**. This section describes architectural and implementation options for providing your own feed.

Feed actions and Lifecycle Operations

The *feed action* is a normal OpenWhisk *action*, but it should accept the following parameters:

- **lifecycleEvent**: one of 'CREATE', 'DELETE', 'PAUSE', or 'UNPAUSE'
- **triggerName**: the fully-qualified name of the trigger which contains events produced from this feed.
- **authKey**: the Basic auth. credentials of the OpenWhisk user who owns the trigger just mentioned

The feed action can also accept any other parameters it needs to manage the feed. For example, the Cloudant changes feed action expects to receive parameters including *'dbname'*, *'username'*, etc.

Sequence entity

Actions can be composed into sequences to, in effect, form a new Action. The Sequence entity allows for a simple, convenient way to describe them in the Package Manifest.

Fields

Key Name	Required	Value Type	Default	Description
actions	yes	`list of Action`	N/A	• The required list of two or more actions

Requirements

- The comma separated list of Actions on the actions key SHALL imply the order of the sequence (from left, to right).
- There MUST be two (2) or more actions declared in the sequence.

Notes

- The sequences key exists for convenience; however, it is just one possible instance of a composition of Actions. The composition entity is provided for not only describing sequences, but also for other (future) compositions and additional information needed to compose them. For example, the composition entity allows for more complex mappings of input and output parameters between Actions.

Grammar

```
sequences:
  <sequence name>:
     <Entity schema>
     actions: <ordered list of action names>
  ...
```

Example

```
sequences:
  newbot:
    actions: oauth/login, newbot-setup, newbot-greeting
```

API entity

This entity allows manifests to link Actions to be made available as HTTP-based API endpoints as supported by the API Gateway service of OpenWhisk.

This entity declaration is intended to provide grammar for the experimental API *(see https://github.com/apache/incubator-openwhisk/blob/master/docs/apigateway.md* and shown using a "book club" example:

CLI Example

```
$ wsk api create -n "Book Club" /club /books get getBooks
$ wsk api create /club /books post postBooks
$ wsk api create /club /books put putBooks
$ wsk api create /club /books delete deleteBooks
```

the above would translate to the following grammars in the pkg. spec. to a new-top level keyname "apis" in the manifest:

Grammar

```
apis:
  <API name>:                    # descriptive name
    description: <string>        # optional, description
    <basepath>:                  # shared basepath
      <path>:
         <action name>: get | post | put | delete
         ...
      ...
```

Note

- There can be more than one set of named <path> actions under the same <basepath>.

Example

A somewhat simplified grammar is also supported that allows single-line definition of Actions (names) along with their HTTP verbs.

```
apis:
  book-club:
    club:
      books:
        getBooks: get
        postBooks: post
        putBooks: put
        deleteBooks: delete
      members:
        listMembers: get
```

Requirements

- The API entity's name (i.e., `<API Name>`) MUST be less than or equal to 256 characters.

Notes

- The API entity within the OpenWhisk programming model is considered outside the scope of the Package. This means that API information will not be returned when using the OpenWhisk Package API:
  - `wsk package list <package name>`
- However, it may be obtained using the Trigger API:
  - `wsk api list -v`

Package entity

The Package entity schema is used to define an OpenWhisk package within a manifest.

Fields

Key Name	Required	Value Type	Default	Description
version	yes	`version`	N/A	The required user-controlled version for the Package.

Key Name	Required	Value Type	Default	Description
license	no	`string`	`N/A`	The required value that indicates the type of license the Package is governed by. The value is required to be a valid Linux-SPDX value. See https://spdx.org/licenses/.
credential	no	`string`	`N/A`	The optional Credential used for all entities within the Package. The value is either: Contains either: • A credential string. • The optional name of a credential (e.g., token) that is defined elsewhere.
dependencies	no	list of Dependency	N/A	The optional list of external OpenWhisk packages the manifest needs deployed before it can be deployed.
repositories	no	list of `Repository`	N/A	The optional list of external repositories that contain functions and other artifacts that can be found by tooling.
actions	no	list of `Action`	N/A	Optional list of OpenWhisk Action entity definitions.
sequences	no	list of Sequence	N/A	Optional list of OpenWhisk Sequence entity definitions.
triggers	no	list of `Trigger`	N/A	Optional list of OpenWhisk Trigger entity definitions.
rules	no	list of `Rule`	N/A	Optional list of OpenWhisk Rule entity definitions.
feeds	no	list of `Feed`	N/A	Optional list of OpenWhisk Feed entity definitions.
apis	no	list of API	N/A	Optional list of API entity definitions.
compositions *(Not yet supported)*	no	list of `Composition`	N/A	Optional list of OpenWhisk Composition entity definitions.

Requirements

- The Package `name` MUST be less than or equal to 256 characters.
- The Package entity schema includes all general Entity Schema fields in addition to any fields declared above.
- A valid Package `license` value MUST be one of the Linux SPDX license values; for example: `Apache-2.0` or `GPL-2.0+`, or the value '`unlicensed`'.
- Multiple (mixed) licenses MAY be described using using NPM SPDX license syntax.
- A valid Package entity MUST have one or more valid Actions defined.

Notes

- Currently, the '`version`' value is not stored in Apache OpenWhisk, but there are plans to support it in the future.
- Currently, the '`license`' value is not stored in Apache OpenWhisk, but there are plans to support it in the future.

- The Trigger and API entities within the OpenWhisk programming model are considered outside the scope of the Package. This means that Trigger and API information will not be returned when using the OpenWhisk Package API:
  - `wsk package list <package name>`
- However, their information may be retrieved using respectively:
  - `wsk trigger list –v`
  - `wsk api list -v`

Grammar

```
<packageName>:
    <Entity schema>
    version: <version>
    license: <string>
    repositories: <list of Repository>
    actions: <list of Action>
    sequences: <list of Sequence>
    triggers: <list of Trigger>
    rules: <list of Rule>
    feeds: <list of Feed>
    apis: <list of API>
    compositions: <list of Composition> # Not yet supported
```

Example

```
my_whisk_package:
  description: A complete package for my awesome action to be deployed
  version: 1.2.0
  license: Apache-2.0
  actions:
    my_awsome_action:
      <Action schema>
  triggers:
    trigger_for_awesome_action:
      <Trigger schema>
  rules:
    rule_for_awesome_action>
      <Rule schema>
```

Composition entity *(Not yet supported)*

The Composition entity schema contains information to declare compositions of OpenWhisk Actions. Currently, this includes Action Sequences where Actions can be composed of two or more existing Actions.

Fields

Key Name	Required	Value Type	Default	Description
type	no	`string`	`sequence`	The optional type of Action composition. *Note: currently only 'sequence' is supported.*

Key Name	Required	Value Type	Default	Description
inputs	no	`list of parameter`	N/A	The optional list of parameters for the Action composition (e.g., Action Sequence).
outputs	no	`list` of `parameter`	N/A	The optional outputs from the Entity.
sequence	no	`ordered list` of `Action` (names)	`N/A`	The optional expression that describes the connections between the Actions that comprise the Action sequence composition.
parameterMappings	no	TBD	`N/A`	The optional expression that describes the mappings of parameter (names and values) between the outputs of one Action to the inputs of another Action. Note: Currently, mappings are not supported and JSON objects are passed between each Action in a sequence. At this time, it is assumed that the Actions in a sequence are designed to work together with no output to input mappings being performed by the OpenWhisk platform.

499 *Requirements*

500 • The Composition name (i.e., `<compositionName>` MUST be less than or equal to 256 characters.
501 • The Composition entity schema includes all general Entity Schema fields in addition to any fields
502 declared above.

503 *Grammar*

```
<compositionName>:
  <Entity schema> # Common to all OpenWhisk Entities
  type: <string>
  inputs:
    <list of parameter>
  outputs:
    <list of parameter>
  sequence:
    actions: <ordered list of action names>
  parameterMappings:
    # TBD. This is a future use case.
```

504 *Example: multi-line sequence*

```
my_action_sequence:
  type: sequence
  sequence:
    actions: action_1, action_2, action_3
  inputs:
    simple_input_string: string
  outputs:
    annotated_output_string: string
```

Extended Schema

Dependencies

The dependencies section allows you to declare other OpenWhisk packages that your application or project (manifest) are dependent on. A Dependency is used to declare these other packages which deployment tools can use to automate installation of these pre-requisites.

Fields

Key Name	Required	Value Type	Default	Description
location	yes	`string`	`N/A`	The required location of the dependent package.
version	yes	`version`	`N/A`	The required version of the dependent package.
inputs	no	`list of parameter`	`N/A`	The optional Inputs to the dependent package.

Requirements

- No additional requirements.

Notes

- The <package_name> is a local alias for the actual package name as described in the referenced package. The referenced package would have its own Manifest file that would include its actual Package name (and the one that would be used by the wskdeploy tool to replace the local alias).
- The 'version' parameter is currently used to specify a branch in GitHub and defaults to "master", this behavior may change in upcoming releases of the specification.
- The experimental key name 'name' is only valid when the deprecated 'package' keyword has been used instead of the favored key 'packages'. If it is used within the 'packages' structure, it will cause a warning and be ignored as it is redundant to the <packageName>.

Grammar

```
<package_name>:
  <Entity schema>
  location: <GitHub URL> |
  version: 1.0.1
  inputs:
    <list of parameter>
```

Example

```
dependencies:
  status_update:
    location: github.com/myrepo/statusupdate
    version: 1.0
  database_pkg:
    location: /whisk.system/couchdb
    inputs:
      dbname: MyAppsDB
```

Repository

A repository defines a named external repository which contains (Action) code or other artifacts package processors can access during deployment.

Fields

Key Name	Required	Value Type	Default	Description
description	no	`string256`	N/A	Optional description for the Repository.
url	yes	`string`	N/A	Required URL for the Repository.
credential	no	`Credential`	N/A	Optional name of a Credential defined in the Package that can be used to access the Repository.

Requirements

- The Repository name (i.e., `<repositoryName>` MUST be less than or equal to 256 characters.
- Description string values SHALL be limited to 256 characters.

Grammar

Single-line (no credential)

```
<repositoryName>: <repository_address>
```

Multi-line

```
<repositoryName>:
  description: <string256>
  url: <string>
  credential: <Credential>
```

Example

```
my_code_repo:
  description: My project's code repository in GitHub
  url: https://github.com/openwhisk/openwhisk-package-rss
```

Credential

A Credential is used to define credentials used to access network accessible resources. Fields

Key Name	Required	Value Type	Default	Description
protocol	no	`string`	N/A	Optional protocol name used to indicate the authorization protocol to be used with the Credential's token and other values.
tokenType	yes	`string`	password	Required token type used to indicate the type (format) of the token string within the supported types allowed by the protocol.

Key Name	Required	Value Type	Default	Description
token	yes	`string`	`N/A`	Required token used as a credential for authorization or access to a networked resource.
description	no	`string256`	N/A	Optional description for the Credential.
keys	no	`map` of `string`	N/A	Optional list of protocol-specific keys or assertions.

Requirements

- The Credential name (i.e., `<credentialName>` MUST be less than or equal to 256 characters.
- Description string values SHALL be limited to 256 characters.

Valid protocol values

Protocol Value	Valid Token Type Values	Description
`plain`	N/A	Basic (plain text) username-password (no standard).
`http`	basic_auth	HTTP Basic Authentication Protocol.
`xauth`	X-Auth-Token	HTTP Extended Authentication Protocol (base-64 encoded Tokens).
`oauth`	bearer	Oauth 2.0 Protocol
`ssh`	identifier	SSH Keypair protocol (e.g., as used in OpenStack)

Grammar

```
Credential:
  type: Object
  properties:
    protocol:
      type: string
      required: false
    tokenType:
      type: string
      default: password
    token:
      type: string
    keys:
      type: map
      required: false
      entry_schema:
        type: string
    user:
      type: string
      required: false
```

Notes

- The use of transparent user names (IDs) or passwords are not considered best practice.

Examples

Plain username-password (no standardized protocol)

```
inputs:
  my_credential:
    type: Credential
      properties:
        user: my_username
        token: my_password
```

HTTP Basic access authentication

```
inputs:
  my_credential:
    type: Credential
    description: Basic auth. where <username>:<password> are a single string
    properties:
      protocol: http
      token_type: basic_auth
      # Note: this would be base64 encoded before transmission by any impl.
      token: myusername:mypassword
```

X-Auth-Token

```
inputs:
  my_credential:
    type: Credential
    description: X-Auth-Token, encoded in Base64
    properties:
      protocol: xauth
      token_type: X-Auth-Token
      # token encoded in Base64
      token: 604bbe45ac7143a79e14f3158df67091
```

OAuth bearer token

```
inputs:
  my_credential:
    type: Credential
    properties:
      protocol: oauth2
      token_type: bearer
      # token encoded in Base64
      token: 8ao9nE2DEjr1zCsicWMpBC
```

SSH Keypair

```
inputs:
  my_ssh_keypair:
    type: Credential
    properties:
      protocol: ssh
      token_type: identifier
      # token is a reference (ID) to an existing keypair (already installed)
```

```
      token: <keypair_id>
```

Package Artifacts

Package Manifest File

The Package Manifest file is the primary OpenWhisk Entity used to describe an OpenWhisk Package and all necessary **schema** and **file** information needed for deployment. It contains the Package entity schema described above.

Deployment File

The Deployment file is used in conjunction with a corresponding Package Manifest file to provide configuration information (e.g., input parameters, authorization credentials, etc.) needed to deploy, configure and run an OpenWhisk Package for a target Cloud environment.
Fields

The manifest and Deployment files are comprised of the following entities:

Application

An optional, top-level key that describes a set of related Packages that together comprise a higher-order application.

Fields

Key Name	Required	Value Type	Default	Description
version	no	`version`	N/A	The optional user-controlled version for the Application.
name	no	`string256`	N/A	The optional name of the application. Note: This key is only valid in the singular 'package' grammar.
namespace	no	`string`	N/A	The optional namespace for the application (and default namespace for its packages where not specified).
credential	no	`string`	N/A	The optional credential for the application (and default credential for its packages where not specified).
package	maybe	`package (singular)`	N/A	The required package definition when the key name 'packages' (plural) is not present.
packages	maybe	`list of package (plural)`	N/A	The required list of one or more package definitions when the key name 'package' (singular) is not present.

Grammar (singular)

```
application:
  version: <version>
```

```
  name: <string256>
  namespace: <string>
  credential: <string>
  package:
    <package definition>
```

574 *Grammar (plural)*

```
application:
  version: <version>
  name: <string256>
  namespace: <string>
  credential: <string>
  packages:
    <list of package definitions>
```

575 *Requirements*

576 • The keys under the application key (e.g., name, namespace, credential and packages) are only used in
577 a manifest or deployment file if the optional application key is used.
578 • Either the key name 'package' (singular) or the key name 'packages' (plural) MUST be provided but
579 not both.
580 ○ If the 'package' key name is provided, its value must be a valid package definition.
581 ○ If the 'packages' key name is provided, its value must be one or more valid package
582 definitions.

583 *Notes*

584 • Currently, the OpenWhisk platform does not recognize the Application entity as part of the
585 programming model; it exists as a higher order grouping concept only in this specification. Therefore,
586 there is no data stored within OpenWhisk for the Application entity.
587 • The keyword 'package' and its singular grammar for declaring packages MAY be deprecated in future
588 versions of the specification.

589 *Example*

```
application:
  name: greetings
  namespace: /mycompany/greetings/
  credential: 1234-5678-90abcdef-0000
  packages:
    helloworld:
      inputs:
        city: Boston
      actions:
        hello:
          inputs: # input bindings
            personName: Paul
    ...
```

Example Notes

- A common use would be to associate a namespace (i.e., a target namespace binding) or credential to an application and all included packages automatically inherit that namespace (if applied at that level) unless otherwise provided (similar to style inheritance in CSS).
- The application name would be treated as metadata, perhaps stored in the annotations for the contained entities.

Scenarios and Use cases

Usage Scenarios

User background

The following assumptions about the users referenced in the usage scenarios:

- Experienced developer; knows Java, Node, SQL, REST principles and basic DevOps processes; uses IDEs to develop code locally.
- Limited exposure to Serverless, but interested in trying new technologies that might improve productivity.

Scenario 1: Clone and Create

Deploy an OpenWhisk app (project, set of entities, package, ...) discovered on github. The developer...

1. discovers an interesting git repo containing an OpenWhisk app (project, set of entities, package, ...)
2. clones the repo to local disk.
3. He pushes (deploys) it into one of his OpenWhisk namespaces
4. He checks out the app's behavior using OpenWhisk CLI or OpenWhisk UI

Notes

- while this scenario allows to use the manifest file as a "black box" the manifest format can influence the user experience of a developer trying to read it and understand what it does

Scenario 2: Pushing Updates with versioning

Change a cloned repo that he previously pushed into one of his namespaces. The developer...

1. changes the local repo by editing code and adding and changing entity specifications using local tools (editors, IDEs, ...).
2. bumps version number for package.
3. pushes his updates into the namespace so that the existing entities are changed accordingly.

Scenario 3: Start New Repo with Manifest

Start a new OpenWhisk app (project, set of entities) from scratch. The developer...

1. code files for the actions (e.g. *action1.js, action2.js, action3.js)*
2. creates a LICENSE*.txt file*
3. Creates a **Manifest File** that specifies the set of OpenWhisk entities and their relations (e.g. *manifest.yml).* It also references the LICENSE.txt file.
4. initializes and uploads the set of files as a new git repo.

Notes:

- Creating the initial manifest file should be supported by providing an empty template with syntax examples and other helpful comments

Scenario 4: Export into Repository

Share an existing OpenWhisk app (project, set of entities) with others
so that they can deploy and change it for their purposes. The developer…

1. exports a defined set of entities (a whole namespace?) into a set of files that includes code files, and generated manifest, LICENSE.txt and README files.
2. initializes and uploads the set of files as a new git repo.
   Example: `git init` ... etc.

Scenario 5: Discovery and Import from object store

Discover an OpenWhisk package (manifest) co-located with data in an Object storage service.

This package would include a description of the Actions, Triggers, Rules and Event Sources (or Feeds) necessary to interact with data it is associated with directly from the Object storage repository; thus allowing anyone with access to the data an immediate way to interact and use the data via the OpenWhisk Serverless platform.

Guided examples

This packaging specification grammar places an emphasis on simplicity for the casual developer who may wish to hand-code a Manifest File; however, it also provides a robust optional schema that can be advantaged when integrating with larger application projects using design and development tooling such as IDEs.

This guide will use examples to incrementally show how to use the OpenWhisk Packaging Specification to author increasingly more interesting Package Manifest and Deployment files taking full advantage of the specification's schema.

Please note that the Apache 'wskdeploy' utility will be used to demonstrate output results.

Package Examples

Example 1: Minimal valid Package Manifest

This use case shows a minimal valid package manifest file.

including:

- shows how to declare a Package named '`hello_world_package`'.

Manifest Files

Example 1: Minimum valid Package manifest file

```
package:
  name: hello_world_package
  version: 1.0
  license: Apache-2.0
```

Notes

- Currently, the 'version' and 'license' key values are not stored in Apache OpenWhisk, but there are plans to support it in the future.

Actions Examples

Example 1: The "Hello world" Action

As with most language introductions, in this first example we encode a simple "hello world" action, written in JavaScript, using an OpenWhisk Package Manifest YAML file.

It shows how to:

- declare a single Action named '`hello_world`' within the '`hello_world_package`' Package.
- associate the JavaScript function's source code, stored in the file '`src/hello.js`', to the '`hello_world`' Action.

Manifest File

Example: "Hello world" using a NodeJS (JavaScript) action

```
package:
  name: hello_world_package
  version: 1.0
  license: Apache-2.0
  actions:
    hello_world:
      function: src/hello.js
```

where "`hello.js`", within the package-relative subdirectory named '`src`', contains the following JavaScript code:

```
function main(params) {
    msg = "Hello, " + params.name + " from " + params.place;
    return { greeting:  msg };
}
```

Deploying

```
$ ./wskdeploy -m docs/examples/manifest_hello_world.yaml
```

Invoking

```
$ wsk action invoke hello_world_package/hello_world --blocking
```

Result

The invocation should return an 'ok' with a response that includes this result:

```
"result": {
   "greeting": "Hello, undefined from undefined"
},
```

The output parameter '`greeting`' contains "*undefined*" values for the '`name`' and '`place`' input parameters as they were not provided in the manifest.

Discussion

This "hello world" example represents the minimum valid Manifest file which includes only the required parts of the Package and Action descriptors.

In the above example,

- The Package and its Action were deployed to the user's default namespace using the 'package' name.
  - `/<default namespace>/hello_world_package/hello_world`
- The NodeJS default runtime (i.e., `runtime: nodejs`) was automatically selected based upon the '`.js`' extension on the Action function's source file '`hello.js`'.

Example 2: Adding fixed Input values to an Action

This example builds upon the previous "hello world" example and shows how fixed values can be supplied to the input parameters of an Action.

It shows how to:

- declare input parameters on the action '`hello_world`' using a single-line grammar.
- add '`name`' and '`place`' as input parameters with the fixed values "Sam" and "the Shire" respectively.

Manifest File

Example: "Hello world" with fixed input values for 'name' and 'place'

```
package:
  name: hello_world_package
  version: 1.0
  license: Apache-2.0
  actions:
    hello_world_fixed_parms:
      function: src/hello.js
      inputs:
        name: Sam
        place: the Shire
```

Deployment

```
$ ./wskdeploy -m docs/examples/manifest_hello_world_fixed_parms.yaml
```

Invoking

```
$ wsk action invoke hello_world_package/hello_world_fixed_parms --blocking
```

Result

The invocation should return an 'ok' with a response that includes this result:

```
"result": {
  "greeting": "Hello, Sam from the Shire"
},
```

Discussion

In this example:

- The value for the '`name`' input parameter would be set to "`Sam`".
- The value for the '`place`' input parameter would be set to "`the Shire`".
- The wskdeploy utility would infer that both '`name`' and '`place`' input parameters to be of type '`string`'.

Example 3: "Hello world" with typed input and output parameters

This example shows the "Hello world" example with typed input and output Parameters.

It shows how to:

- declare input and output parameters on the action 'hello_world' using a simple, single-line grammar.
- add two input parameters, 'name' and 'place', both of type 'string' to the 'hello_world' action.
- add an 'integer' parameter, 'age', to the action.
- add a 'float' parameter, 'height', to the action.
- add two output parameters, 'greeting' and 'details', both of type 'string', to the action.

Manifest File

Example: "Hello world" with typed input and output parameter declarations

```
package:
  name: hello_world_package
  ... # Package keys omitted for brevity
  actions:
    hello_world_typed_parms:
      function: src/hello_plus.js
      inputs:
        name: string
        place: string
        children: integer
        height: float
      outputs:
        greeting: string
        details: string
```

where the function 'hello_plus.js', within the package-relative subdirectory named 'src', is updated to use the new parameters:

```
function main(params) {
    msg = "Hello, " + params.name + " from " + params.place;
    family = "You have " + params.children + " children ";
    stats = "and are " + params.height + " m. tall.";
    return { greeting:  msg, details: family + stats };
}
```

Deployment

```
$ ./wskdeploy -m docs/examples/manifest_hello_world_typed_parms.yaml
```

Invoking

```
$ wsk action invoke hello_world_package/hello_world_typed_parms --blocking
```

Result

The invocation should return an 'ok' with a response that includes this result:

```
"result": {
  "details": "You have 0 children and are 0 m. tall.",
```

```
  "greeting": "Hello,  from "
},
```

Discussion

In this example:

- The default value for the '`string`' type is the empty string (i.e., `""`); it was assigned to the '`name`' and '`place`' input parameters.
- The default value for the '`integer`' type is zero (0); it was assigned to the '`age`' input parameter.
- The default value for the '`float`' type is zero (0.0f); it was assigned to the '`height`' input parameter.

Example 4: "Hello world" with advanced parameters

This example builds on the previous '"Hello world" with typed input and output parameters' example with more robust input and output parameter declarations by using a multi-line format for declaration.

This example:

- shows how to declare input and output parameters on the action '`hello_world`' using a multi-line grammar.

Manifest file

If we want to do more than declare the type (i.e., '`string`', '`integer`', '`float`', etc.) of the input parameter, we can use specifications the multi-line grammar for Parameters.

Example: input and output parameters with advanced fields

```
package:
  name: hello_world_package
  ... # Package keys omitted for brevity
  actions:
    hello_world_advanced_parms:
      function: src/hello.js
      inputs:
        name:
          type: string
          description: name of person
          default: unknown person
        place:
          type: string
          description: location of person
          value: the Shire
        children:
          type: integer
          description: Number of children
          default: 0
        height:
          type: float
          description: height in meters
          default: 0.0
      outputs:
        greeting:
```

```
          type: string
          description: greeting string
        details:
          type: string
          description: detailed information about the person
```

Deployment

```
$ ./wskdeploy -m docs/examples/manifest_hello_world_advanced_parms.yaml
```

Invoking

```
$ wsk action invoke hello_world_package/hello_world_advanced_parms --
blocking
```

Invoking the action would result in the following response:

```
"result":
  "details": "You have 0 children and are 0 m. tall.",
  "greeting": "Hello, unknown person from the Shire"
},
```

Discussion

- Describing the input and output parameter types, descriptions, defaults and other data:
  - enables tooling to validate values users may input and prompt for missing values using the descriptions provided.
  - allows verification that outputs of an Action are compatible with the expected inputs of another Action so that they can be composed in a sequence.
- The '`name`' input parameter was assigned the '`default`' key's value "`unknown person`".
- The '`place`' input parameter was assigned the '`value`' key's value "`the Shire`".

Example 5: Adding a Trigger and Rule to “hello world”

This example will demonstrate how to define a Trigger that is compatible with the basic ‘hello_world’ Action and associate it using a Rule.

Manifest File

Example: “Hello world” Action with a compatible Trigger and Rule

```
package:
  name: hello_world_package
  ... # Package keys omitted for brevity
  actions:
    hello_world_triggerrule:
      function: src/hello_plus.js
      inputs:
        name: string
        place: string
        children: integer
        height: float
```

```
      outputs:
        greeting: string
        details: string

  triggers:
    meetPerson:
      inputs:
        name: Sam
        place: the Shire
        children: 13
        height: 1.2

  rules:
    myPersonRule:
      trigger: meetPerson
      action: hello_world_triggerrule
```

Deployment

without the Deployment file:

```
$ wskdeploy -m docs/examples/manifest_hello_world_triggerrule.yaml
```

Invoking

First, let's try *"invoking"* the ‘`hello_world_triggerrule'` Action directly without the Trigger.

```
$ wsk action invoke hello_world_package/hello_world_triggerrule --blocking
```

Invoking the action would result in the following response:

```
"result": {
  "details": "You have 0 children and are 0 m. tall.",
  "greeting": "Hello,  from "
},
```

As you can see, the results verify that the default values (i.e., empty strings and zeros) for the input parameters on the '`hello_world_triggerrule'` Action were used to compose the '`greeting`' and '`details`' output parameters. This result is expected since we did not bind any values or provide any defaults when we defined the `'hello_world_triggerrule`' Action in the manifest file.

Triggering

Instead of invoking the Action, here try *"firing"* the '`meetPerson`' Trigger:

```
$ wsk trigger fire meetPerson
```

Result

which results in an Activation ID:

```
ok: triggered /_/meetPerson with id a8e9246777a7499b85c4790280318404
```

The 'meetPerson' Trigger is associated with 'hello_world_triggerrule' Action the via the 'meetPersonRule' Rule. We can verify that firing the Trigger indeed cause the Rule to be activated which in turn causes the Action to be invoked:

```
$ wsk activation list

d03ee729428d4f31bd7f61d8d3ecc043 hello_world_triggerrule
3e10a54cb6914b37a8abcab53596dcc9 meetPersonRule
5ff4804336254bfba045ceaa1eeb4182 meetPerson
```

we can then use the 'hello_world_triggerrule' Action's Activation ID to see the result:

```
$ wsk activation get d03ee729428d4f31bd7f61d8d3ecc043
```

to view the actual results from the action:

```
"result": {
   "details": "You have 13 children and are 1.2 m. tall.",
   "greeting": "Hello, Sam from the Shire"
}
```

which verifies that the parameters bindings of the values (i.e., "Sam" (name), "the Shire" (place), '13' (age) and '1.2' (height)) on the Trigger were passed to the Action's corresponding input parameters correctly.

Discussion

- Firing the 'meetPerson' Trigger correctly causes a series of non-blocking "*activations*" of the associated 'meetPersonRule' Rule and subsequently the 'hello_world_triggerrule' Action.
- The Trigger's parameter bindings were correctly passed to the corresponding input parameters on the 'hello_world_triggerrule' Action when "firing" the Trigger.

Example 6: Using a Deployment file to bind Trigger parameters

This example builds on the previous Trigger-Rule example and will demonstrate how to use a Deployment File to bind values for a Trigger's input parameters when applied against a compatible Manifest File

Manifest File

Let's use a variant of the Manifest file from the previous Trigger Rule example; however, we will leave the parameters on the 'meetPerson' Trigger unbound and only with type declarations.

Example: "Hello world" Action, Trigger and Rule with no Parameter bindings

```
package:
  name: hello_world_package
  ... # Package keys omitted for brevity
  actions:
    hello_world_triggerrule:
      function: src/hello_plus.js
      runtime: nodejs
      inputs:
        name: string
        place: string
```

```
        children: integer
        height: float
      outputs:
        greeting: string
        details: string

  triggers:
    meetPerson:
      inputs:
        name: string
        place: string
        children: integer
        height: float

  rules:
    meetPersonRule:
      trigger: meetPerson
      action: hello_world_triggerrule
```

Deployment File

Let's create a Deployment file that is designed to be applied to the Manifest file (above) which will contain the parameter bindings (i.e., the values) for the 'meetPerson' Trigger.

Example: Deployment file that binds parameters to the 'meetPerson' Trigger

```
application:
  package:
    hello_world_package:
      triggers:
        meetPerson:
          inputs:
            name: Elrond
            place: Rivendell
            children: 3
            height: 1.88
```

As you can see, the package name 'hello_world_package' and the trigger name 'meetPerson' both match the names in the corresponding Manifest file.

Deploying

Provide the Manifest file and the Deployment file to the wskdeploy utility:

```
$ wskdeploy -m docs/examples/manifest_hello_world_triggerrule_unbound.yaml
-d docs/examples/deployment_hello_world_triggerrule_bindings.yaml
```

Triggering

Fire the 'meetPerson' Trigger:

```
$ wsk trigger fire meetPerson
```

Result

Find the activation ID for the "hello_world_triggerrule' Action that firing the Trigger initiated and get the results from the activation record.

```
$ wsk activation list

3a7c92468b4e4170bc92468b4eb170f1 hello_world_triggerrule
afb2c02bb686484cb2c02bb686084cab meetPersonRule
9dc9324c601a4ebf89324c601a1ebf4b meetPerson

$ wsk activation get 3a7c92468b4e4170bc92468b4eb170f1

"result": {
   "details": "You have 3 children and are 1.88 m. tall.",
   "greeting": "Hello, Elrond from Rivendell"
}
```

Discussion

- The 'hello_world_triggerrule' Action and the 'meetPerson' Trigger in the Manifest file both had input parameter declarations that had no values assigned to them (only Types).
- The matching 'meetPerson' Trigger in the Deployment file had values bound its parameters.
- The wskdeploy utility applied the parameter values (after checking for Type compatibility) from the Deployment file to the matching (by name) parameters within the Manifest file.

Github feed

This example will install a feed to fire a trigger when there is activity in a specified GitHub repository.

Manifest File

```
git_webhook:
  version: 1.0
  license: Apache-2.0
  feeds:
    webhook_feed:
      version: 1.0
      function: github/webhook.js
      runtime: nodejs@6
```

```
      inputs:
        username:
          type: string
          description: github username
        repository:
          type: string
          description: url of github repository
        accessToken:
          type: string
          description: GitHub personal access token
        events:
          type: string
          description: the github event type

  triggers:
     webhook_trigger:
      action: webhook_feed
```

Deployment File

```
packages:
  git_webhook:
    triggers:
      webhook_trigger:
        inputs:
          username: daisy
          repository: https://github.com/openwhisk/wsktool.git
          accessToken:
          events:push
```

Advanced examples

Github feed advanced

This use case uses the Github feed to create a trigger. When there is any push event, it will send a notification email.

Manifest File

```
git_webhook:
  version: 1.0
  license: Apache-2.0
  action:
    emailNotifier:
      version: 1.0
      function: src/sendemail.js
      runtime: nodejs
      inputs:
        email: string
        title: string
  rules:
    githubNotifier:
```

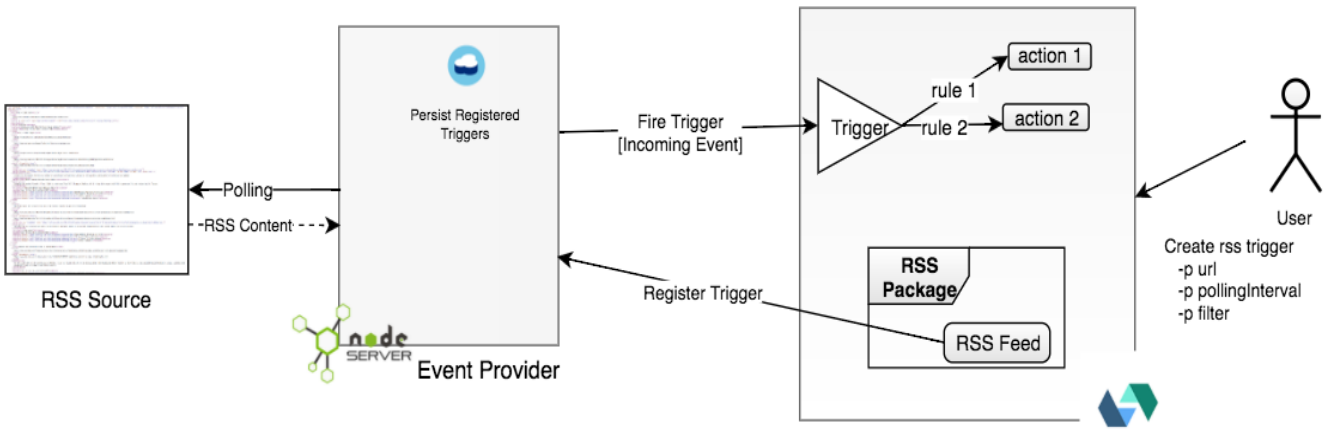
```
      trigger: webhook_trigger
      action: emailNotifier
```

Deployment File

```
packages:
  git_webhook:
    feeds:
      webhook_feed:
        inputs:
          email: daisy@company.com
          title: Github Push Notification
```

RSS Package

The RSS package provides RSS/ATOM feeds which can receive events when a new feed item is available. It also defines a trigger to listen to a specific RSS feed. It describes the OpenWhisk package reposited here:
https://github.com/openwhisk/openwhisk-package-rss.



Manifest File

with inline values (no Deployment File)

This example makes use of in-line "values" where the developer does not intend to use a separate Deployment file:

```
rss:
  version: 1.0
  license: Apache-2
  description: RSS Feed package
  inputs:
    provider_endpoint:
      value: http://localhost:8080/rss
      type: string
      description: Feed provider endpoint
```

```
  feeds:
    rss_feed:
      version: 1.0
      function: feeds/feed.js
      runtime: nodejs@6
      inputs:
        url:
          type: string
          description: url to RSS feed
          value: http://rss.nytimes.com/services/xml/rss/nyt/HomePage.xml
        pollingInterval:
          type: string
          description: Interval at which polling is performed
          value: 2h
        filter:
          type: string
          description: Comma separated list of keywords to filter on

  triggers:
    rss_trigger:
      action: rss_feed
```

Deployment File

Alternatively, a Deployment File could have provided the same values (bindings) in this way:

```
packages:
  rss:
    inputs:
      provider_endpoint: http://localhost:8080/rss

    feeds:
      rss_feed:
        inputs:
          url: http://rss.nytimes.com/services/xml/rss/nyt/HomePage.xml
          pollingInterval: 2h
```

Using such a deployment file, allows for more flexibility and the resulting Manifest file would not have needed any '**value**' fields.

Polygon Tracking

This use case describes a microservice composition using Cloudant and a Push Notification service to enable location tracking for a mobile application. The composition uses Cloudant to store polygons that describe regions of interests, and the latest known location of a mobile user. When either the polygon set or location set gets updated, we use the Cloudant Geo capabilities to quickly determine if the new item satisfies a geo query like "is covered by" or "is contained in". If so, a push notification is sent to the user.

Manifest File:

```
application:
  name: PolygonTracking
```

```
namespace: polytrack

packages:
  polytrack:

    triggers:
      pointUpdate:
        <feed>

      polygonUpdate:
        <feed>

    actions:
      superpush:
        inputs:
          appId: string
          appSecret: string

      pointGeoQuery:
        inputs:
          username: string
          password: string
          host: string
          dbName: string
          ddoc: string
          iName: string
          relation: string
        outputs:
          cloudantResp: json

      createPushParamsFromPointUpdate:
        <mapper>

      polygonGeoQuery:
        inputs:
          username: string
          password: string
          host: string
          dbName: string
          ddoc: string
          iName: string
          relation: string
        outputs:
          cloudantResp: json

      createPushParamsFromPolygonUpdate:
        <mapper>

    Rules:
      whenPointUpdate:
        trigger:
          pointUpdate
        action:
          handlePointUpdate
```

```
        whenPointUpdate:
          trigger:
            polygonUpdate
          action:
            handlePolygonUpdate

      Composition:
        handlePolygonUpdate:
          sequence:
createGeoQueryFromPolygonUpdate,polygonGeoQuery,createPushParamsFromPolygo
nUpdate,superpush
```

863 ***Deployment File:***

```
application:
  name: PolygonTracking
  namespace: polytrack

  packages:

    myCloudant:
      <bind to Cloudant at whisk.system/Cloudant>

    polytrack:

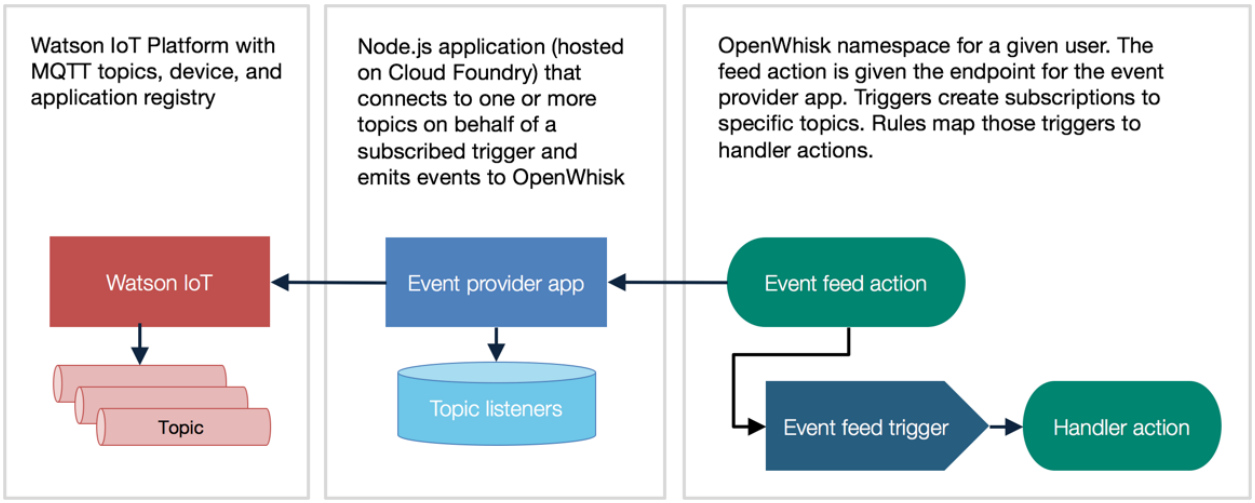
      indexName: $GEOIDX
      relation: $COVEREDBY
      username: $CLOUDANT_username
      password: $CLOUDANT_password
      host: $CLOUDANT_host
      dbName: $POLYDB
  polygonGeoQuery:
    inputs:
      designDoc: $DESIGNDOC
      indexName: $GEOIDX
      relation: $COVERS
      username: $CLOUDANT_username
      password: $CLOUDANT_password
      host: $CLOUDANT_host
      dbName: $POLYDB
```

MQTT Package (tailored for Watson IoT)

The MQTT package that integrates with Watson IoT provides message topic feeds which can receive events when a message is published. It also defines a trigger to listen to a specific MQTT topic It describes the OpenWhisk package reposited here: https://github.com/krook/openwhisk-package-mqtt-watson.



Manifest File

with inline values (no Deployment File)

This example makes use of in-line "values" where the developer does not intend to use a separate Deployment file:

```
mqtt_watson:
  version: 1.0
  license: Apache-2
  description: MQTT Feed package for Watson IoT
  inputs:
    provider_endpoint:
      value: http://localhost:8080/mqtt-watson
      type: string
      description: Feed provider endpoint

  feeds:
    mqtt_watson_feed:
      version: 1.0
      function: feeds/feed-action.js
      runtime: nodejs@6
      inputs:
        url:
          type: string
          description: URL to Watson IoT MQTT feed
          value: ssl://a-123xyz.messaging.internetofthings.ibmcloud.com:8883
        topic:
          type: string
          description: Topic subscription
          value: iot-2/type/+/id/+/evt/+/fmt/json
        apiKey:
          type: string
          description: Watson IoT API key
          value: a-123xyz
        apiToken:
          type: string
          description: Watson IoT API token
          value: +-derpbog
        client:
          type: string
          description: Application client id
          value: a:12e45g:mqttapp

  triggers:
    mqtt_watson_trigger:
      action: mqtt_watson_feed
```

Deployment File

Alternatively, a Deployment File could have provided the same values (bindings) in this way:

```
packages:
```

```
mqtt_watson:
  inputs:
    provider_endpoint: http://localhost:8080/mqtt-watson

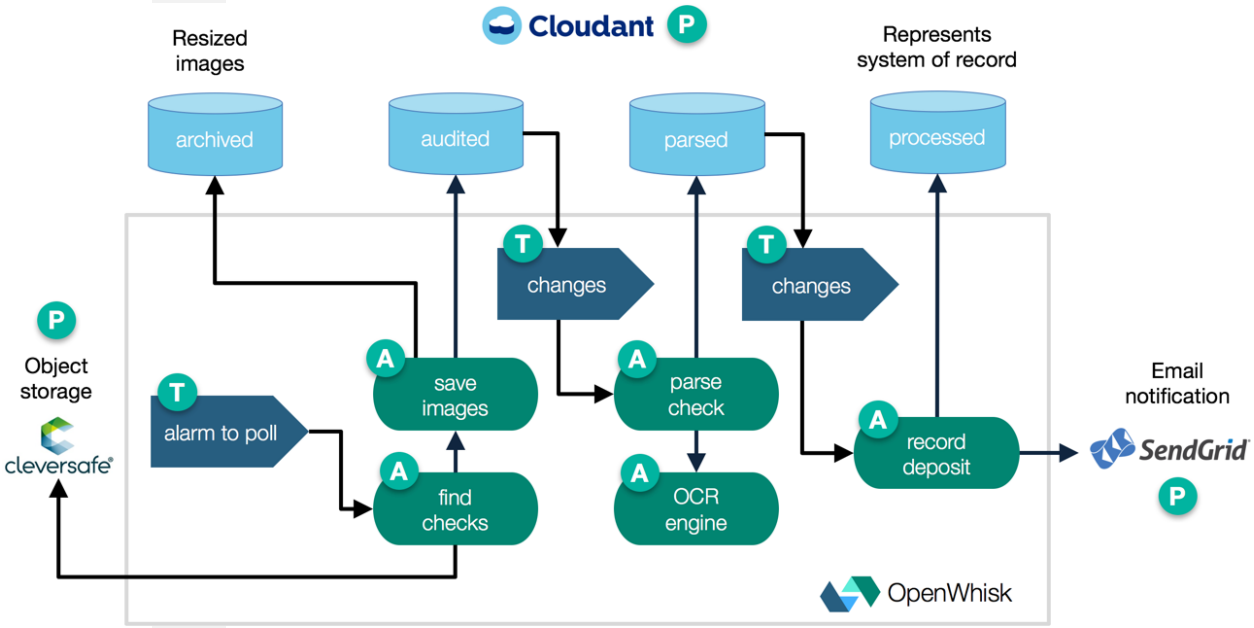
  feeds:
    mqtt_watson_feed:
      inputs:
        url: ssl://a-123xyz.messaging.internetofthings.ibmcloud.com:8883
        topic: iot-2/type/+/id/+/evt/+/fmt/json
        apiKey: a-123xyz
        apiToken: +-derpbog
        client: a:12e45g:mqttapp
```

Using such a deployment file, allows for more flexibility and the resulting Manifest file would not have needed any '**value**' fields.

Check deposit processing with optical character recognition

This use case demonstrates an event-driven architecture that processes the deposit of checks to a bank account using optical character recognition. It relies on Cloudant and SoftLayer Object Storage. On premises, it could use CouchDB and OpenStack Swift. Other storage services could include FileNet or Cleversafe. Tesseract provides the OCR library.

This application uses a set of actions and triggers linked by rules to process images that are added to an object storage service. When new checks are detected a workflow downloads, resizes, archives, and reads the checks then it invokes an external system to handle the transaction.



895 ***Manifest File:***

```

```

Event Sources

OpenWhisk is designed to work with any Event Source, either directly via published APIs from the Event Source's service or indirectly through Feed services that act as an Event Source on behalf of a service. This section documents some of these Event Sources and/or Feeds using this specification's schema.

Curated Feeds

The following Feeds are supported by the Apache OpenWhisk platform. They are considered "curated" since they are maintained alongside the Apache OpenWhisk open source code to guarantee compatibility. More information on curated feeds can be found here: https://github.com/apache/incubator-openwhisk/blob/master/docs/feeds.md.

Alarms

The `/whisk.system/alarms` package can be used to fire a trigger at a specified frequency. This is useful for setting up recurring jobs or tasks, such as invoking a system backup action every hour.

Package Manifest

The "alarms" Package Manifest would appear as follows:

```
# shared system package providing the alarms feed action
alarms:
  version: 1.0
  license: Apache-2
  description: Alarms and periodic utility

  actions:
    alarm:
      function: action/alarm.js
      description: Fire trigger when alarm occurs
      feed: true
      inputs:
        package_endpoint:
          type: string
          description: The alarm provider endpoint with port
        cron:
          type: string
          description: UNIX crontab syntax for firing trigger in
Coordinated Universal Time (UTC).
          required: true
        trigger_payload:
          type: object
          description: The payload to pass to the Trigger, varies
          required: false
        maxTriggers:
          type: integer
          default: 1000
          required: false

  feeds:
```

```
    location: TBD
    credential: TBD
    operations:
      CREATE:
        TBD
      DELETE:
        TBD
    action: alarm
```

Cloudant

The `/whisk.system/cloudant` package enables you to work with a Cloudant database. It includes the following actions and feeds.

Package Manifest

The "cloudant" Package Manifest would appear as follows:

```
TBD
```

Public Sources

The following examples are Event Sources that can provide event data to OpenWhisk. We describe them here using this specification's schema.

GitHub WebHook

Note: the GitHub WebHook is documented here: https://developer.github.com/webhooks/.

A sample description of the GitHub Event Source and its "create hook" API would appear as follows:

```
TBD
```

Other Considerations

Tooling interaction

Using package manifest directly from GitHub

GitHub is an acknowledged as a popular repository for open source projects which may include OpenWhisk Packages along with code for Actions and Feeds. It is easily envisioned that the Package Manifest will commonly reference GitHub as a source for these artifacts; this specification will consider Github as being covered by the general Catalog use case.

Using package manifest in archive (e.g., ZIP) file

Compressed packaging, including popular ZIP tools, is a common occurrence for popular distribution of code which we envision will work well with OpenWhisk Packages; however, at this time, there is no formal description of its use or interaction. We leave this for future consideration.

Simplification of WebHook Integration

Using RESTify

One possible instance of a lightweight framework to build REST APIs in Nodejs to export WebHook functionality. See https://www.npmjs.com/package/restify
RESTify (over Express) provides help in the areas of versioning, error handling (retry, abort) and content-negotiation. It also provides built in DTrace probes that identify application performance problems.

Enablement of Debugging for DevOps

Isolating and debugging "bad" Actions using (local) Docker

Simulate Inputs at time of an Action failure/error condition, isolate it and run it in a "debug" mode.

Considerations include, but are not limited to:

- Isolation on separate "debug" container
- Recreates "inputs" at time of failure
- Possibly recreates message queue state
- Provides additional stacktrace output
- Provides means to enable "debug" trace output
- Connectivity to "other" debug tooling

Using software debugging (LLDB) frameworks

This is a topic for future use cases and integrations. Specifically, working with LLDB frameworks will be considered. See http://lldb.llvm.org/.
